three Fansidar tablets. She was advised to end her holiday after only two weeks. She had no history of contact with jaundice, and the other members of her party were well.

Her gastrointestinal upset had settled by the time she arrived in Nottingham. On admission to hospital she was not jaundiced but was dehydrated with a temperature of 38.5°C. Analysis of her urine showed a trace of albumin and microscopic haematuria. Investigations showed creatinine concentration 83 μmol/l (0.94 mg/100 ml), alkaline phosphatase activity 89 IU/l, bilirubin concentration 11 μmol/l (0.64 mg/100 ml), alanine aminotransferase activity 89 IU/l, and prothrombin time 14 seconds. She developed progressive jaundice during the first week (bilirubin concentration increased to 385 μmol/l (22.5 mg/100 ml)), results of the tests of her liver enzymes deteriorated (alkaline phosphatase activity increased to 1468 IU/l), and prothrombin time failed to clot. She was advised to end her holiday after only two days and was admitted to hospital.

During the next week she was delirious and had hepatic and oliguric renal failure. The skin eruption progressed to a bullous epidermal necrolysis affecting the whole body and was associated with oral and genital ulceration. Cultures of blood, urine, faeces, liver, and bone marrow yielded negative results; microscopic examination of faeces, sputum, and blood films was not helpful; and serological investigations for viruses, bacteria, and parasites also yielded negative results. Histological examination of a needle biopsy specimen of her liver (figure) showed preserved lobular architecture with inflammatory cells, and no red blood cells. All dehydrated patients were either mildly dehydrated or not dehydrated at all three days after the start of diarrhoea. Six of the 18 children under 2 were moderately dehydrated and after death failed to find an aetiology other than this drug.

Skin, liver, and renal toxicity with fever are well known idiosyncratic reactions to sulphonamides. They have occurred separately in patients after use of Fansidar\(^4\) and are presumably due to the sulphonamide (a long acting sulphonamide). No other cases have been reported in which all these toxic manifestations have occurred in the same patient.

We have reported this case to the Committee on the Safety of Medicines and to the manufacturer.

We thank Professor J R Hampton for permission to report this case and Mr Bill Brackenbury for the photography.

Comment

This patient suffered a short fatal illness that was related to prophylactic use of Fansidar. An extensive search while she was alive and after death failed to find an aetiology other than this drug.

Liver biopsy specimen showing inflamed portal tract (top) and well preserved centrilobular zone (bottom). Haematoxylin and eosin × 315 (original magnification).

Cryptosporidiosis in Bangladesh

Despite the large number of enteropathogens identified in recent years the cause of many episodes of diarrhoea remain undetermined. The protozoan Cryptosporidium was first described as a pathogen causing diarrhoea in animals in 1907, and in man in 1976.\(^1\) We were able to identify the cause for diarrhoea in only two thirds of patients coming to our clinic.\(^2\) Cryptosporidiosis is an emerging zoonotic disease, and we therefore began screening for cryptosporidial oocysts in stools of patients visiting our clinic as part of a surveillance programme.\(^3\)

Methods and results

At the Dacca clinic we screened 4% of patients with diarrhoea for cryptosporidial oocysts, using Giemsa stain on faecal smears.\(^4\) All specimens were examined for other common enteropathogens. Thirty eight of 578 smears collected from 1 January to 31 May 1984 were judged to be positive, based on the finding of characteristic oocysts—that is, "holes" in the stained background. These unattached areas sometimes have a faint blue centre with fine red or purple corpuscles.\(^5\) Repeat smears made from refrigerated faeces were stained by a modified acid fast technique; 25 were found to be positive (4.3% of 578 samples).

Eighteen of the 25 patients with cryptosporidiosis were children aged under 2. The disease was found in both sexes and in 21 patients who were moderately to well nourished. Cryptosporidium was the only pathogen in 20 of the 25 patients. Twenty four of them had watery diarrhoea, and 18 were either mildly dehydrated or not dehydrated at all three days after the start of diarrhoea. Six of the 18 children under 2 were moderately dehydrated. Twenty two patients suffered from vomiting and three from mild fever. There was a sudden increase in cases of cryptosporidiosis during the hot, humid weather in March.

In most stool samples we found few segmented leukocytes, no other inflammatory cells, and no red blood cells. All dehydrated patients were successfully rehydrated orally with a rice based solution, and 18 were discharged within 16 hours of admission. A cough was present in six of the patients under 2.

Comment

By studying a small sample of patients we have established that Cryptosporidium exists in Bangladesh. As the sole pathogen it seems to cause a mild, transient, easily managed form of diarrhoea, particularly among young children; only four (16%) of the 25 patients studied were malnourished. The presence of cough in some of the...
children raises the possibility of respiratory infection, as previously reported in man and birds. The oocyst is small enough to be carried by dust. Much of the inhaled dust (possibly in the form of dried powder or dust) is undoubtedly cleared from the tracheobronchial mucosa by the cilia. It is then swallowed and enters the gastrointestinal tract. Many families in Bangladesh keep their poultry and cattle within their premises. Cryptosporidium was recently detected in 14% of calves with diarrhoea and 1%, of calves without diarrhoea at a dairy farm in Bangladesh, as well as in 8.5% of their handlers with diarrhoea. Cryptosporidium was not, however, found in healthy people.1

We are now carrying out more extensive studies.

Relation between dentition and dyspeptic disorders

There is a dearth of information relating the state of the teeth to dyspepsia. This study examined a theory that a disproportionately high number of patients with gastric ulcer and gastric cancer were edentulous.

Patients, methods, and results

From a consecutive series of 400 patients undergoing endoscopy 291 patients fell into the four categories of normal endoscopic findings, gastric ulcer, duodenal ulcer, and gastric cancer; their ages and dentition were recorded. By a subsequent questionnaire to 100 of the patients selected at random we determined the chronological relationship between total loss of natural teeth and onset of dyspepsia and whether the patients wore dentures at meal times. To investigate the association of each category with dyspepsia, allowing for age, we divided the patients into age groups of five years. Within each group we constructed a contingency table of dyspepsia against number of teeth. The theory that most patients with gastric ulcer and gastric cancer are edentulous was confirmed, but this would be expected from their age.

In conclusion, loss of teeth generally precedes dyspepsia and was observed in all clinical categories including patients with normal endoscopic findings. Though lack of teeth may have a role in some cases of dyspepsia, it can be only a minimal one.

We thank Dr M A Maksoud for his help in recording some of the data.

Vascular occlusion and disseminated intravascular coagulation in falciparum malaria

Disseminated intravascular coagulation is the probable cause of the renal, pulmonary, and cerebral complications seen in falciparum but not in benign tertian or quartan malaria, but how the abnormality in coagulation is produced is not known. We suspected that the red blood cells containing parasites might be responsible for initiating disseminated intravascular coagulation in falciparum malaria, and so we compared the procoagulant activity in red blood cells from control patients and from patients infected with Plasmodium falciparum and P vivax.

Patients, methods, and results

Shortening of the one stage plasma recalcification time of normal plasma was taken as an index of red cell procoagulant activity.2 The plasma recalcification time of normal pooled plasma (pool of six samples) obtained on each day of the study was taken as 100% in the calculation of the effect

Cross tabulation of endoscopic findings with dentition in patients with dyspepsia, after allowing for age
